Lecture 15: Linear Programming III

David Woodruff
Carnegie Mellon University

Outline

• Linear Programming Duality

$$P = \max(2x_1 + 3x_2)$$
s.t. $4x_1 + 8x_2 \le 12$
 $2x_1 + x_2 \le 3$
 $3x_1 + 2x_2 \le 4$
 $x_1, x_2 \ge 0$

Since
$$2x_1 + 3x_2 \le 4x_1 + 8x_2 \le 12$$
, we know OPT ≤ 12
Since $2x_1 + 3x_2 \le \frac{1}{2}(4x_1 + 8x_2) \le 6$, we know OPT ≤ 6
Since $2x_1 + 3x_2 \le \frac{1}{3}((4x_1 + 8x_2) + (2x_1 + x_2)) \le 5$, we know OPT ≤ 5

Duality

- We took non-negative linear combinations of the constraints
- How do we find the best upper bound on OPT this way?
- Let $y_1, y_2, y_3 \ge 0$ be the coefficients of our linear combination. Then,

$$4y_1 + 2y_2 + 3y_3 \ge 2$$
 $P = \max(2x_1 + 3x_2)$ $8y_1 + y_2 + 2y_3 \ge 3$ $x_1, y_2, y_3 \ge 0$ $2x_1 + x_2 \le 3$ and we seek $\min(12y_1 + 3y_2 + 4y_3)$ $x_1, x_2 \ge 0$

Primal LP

$$P = \max(2x_1 + 3x_2)$$
s.t. $4x_1 + 8x_2 \le 12$

$$2x_1 + x_2 \le 3$$

$$3x_1 + 2x_2 \le 4$$

$$x_1, x_2 \ge 0$$

$$4y_1 + 2y_2 + 3y_3 \ge 2$$

$$8y_1 + y_2 + 2y_3 \ge 3$$

$$y_1, y_2, y_3 \ge 0$$
and we seek $\min(12y_1 + 3y_2 + 4y_3)$

- If (x_1,x_2) is feasible for the primal, and (y_1,y_2,y_3) feasible for the dual, $2x_1+3x_2\leq 12y_1+3y_2+4y_3$
- If these are equal, we've found the optimal value for both LPs
- $(x_1, x_2) = (\frac{1}{2}, \frac{5}{4})$ and $(y_1, y_2, y_3) = (\frac{5}{16}, 0, \frac{1}{4})$ give the same value 4.75, so optimal

Dual LP

$$4y_1 + 2y_2 + 3y_3 \ge 2$$

 $8y_1 + y_2 + 2y_3 \ge 3$
 $y_1, y_2, y_3 \ge 0$

and we seek $\min(12y_1 + 3y_2 + 4y_3)$

- Let's try do the same thing to the dual:
- $12y_1 + 3y_2 + 4y_3 \ge 4y_1 + 2y_2 + 3y_2 \ge 2$
- $12y_1 + 3y_2 + 4y_3 \ge 8y_1 + y_2 + 2y_3 \ge 3$
- $12y_1 + 3y_2 + 4y_3 \ge \frac{2}{3}(4y_1 + 2y_2 + 3y_2) + (8y_1 + y_2 + 2y_3) \ge \frac{4}{3} + 3$

Dual LP
$$4y_1 + 2y_2 + 3y_{13} \ge 2$$
 $8y_1 + y_2 + 2y_3 \ge 3$ $y_1, y_2, y_3 \ge 0$ $3x_1 + 2x_2 \le 4$ and we seek $\min(12y_1 + 3y_2 + 4y_3)$ $P = \max(2x_1 + 3x_2)$ s.t. $4x_1 + 8x_2 \le 12$ $2x_1 + x_2 \le 3$ $3x_1 + 2x_2 \le 4$

- Take non-negative linear combination of the two constraints
- How do we find the best lower bound on OPT this way?
- Let $x_1, x_2 \ge 0$ be the coefficients of our linear combination. Then,
- $4x_1 + 8x_2 \le 12$, $2x_1 + x_2 \le 3$, $3x_1 + 2x_2 \le 4$, $x_1 \ge 0$, $x_2 \ge 0$ and we seek to maximize $2x_1 + 3x_2$

We got back the primal!

Exercise: Consider the "primal" LP below on the left:

$$P = \max(7x_1 - x_2 + 5x_3)$$

$$S.t. \quad x_1 + x_2 + 4x_3 \le 8$$

$$3x_1 - x_2 + 2x_3 \le 3$$

$$2x_1 + 5x_2 - x_3 \le -7$$

$$x_1, x_2, x_3 \ge 0$$

$$D = \min(8y_1 + 3y_2 - 7y_3)$$

$$S.t. \quad y_1 + 3y_2 + 2y_3 \ge 7$$

$$y_1 - y_2 + 5y_3 \ge -1$$

$$4y_1 + 2y_2 - y_3 \ge 5$$

$$y_1, y_2, y_3 \ge 0$$

Show that the problem of finding the best upper bound obtained using linear combinations of the constraints can be written as the LP above on the right (the "dual" LP). Also, now formulate the problem of finding a lower bound for the dual LP. Show this lower-bounding LP is just the primal (P).

Non-Nice Constraints

$$P = \max(7x_1 - x_2 + 5x_3)$$
s.t. $x_1 + x_2 + 4x_3 \le 8$
 $3x_1 - x_2 + 2x_3 \ge 3$
 $x_1, x_2, x_3 \ge 0$

$$D = \min(8y_1 + 3y_2)$$
s.t. $y_1 + 3y_2 \ge 7$

$$y_1 - y_2 \ge -1$$

$$4y_1 + 2y_2 \ge 5$$

$$y_1 \ge 0, y_2 \le 0$$

Formal Definition of Duality

<u>Primal</u>

```
\begin{aligned} \text{Max } c^T x \\ \text{subject to } Ax & \leq b \\ x & \geq 0 \\ \hline \\ \underline{\text{Dual}} \\ \text{Min } b^T y \\ \text{subject to } A^T y & \geq c \\ y & \geq 0 \end{aligned}
```

- Dual of the dual is the primal!
- Can we get better upper/lower bounds by looking at more complicated combinations of the inequalities, not just linear combinations?

Weak Duality

<u>Primal</u>

Max $c^T x$ subject to $Ax \le b$ $x \ge 0$

Dual

Min b^Ty subject to $A^Ty \ge c$ $y \ge 0$

- (Weak Duality) If x is a feasible solution of the primal, and y is a feasible solution of the dual, then $c^Tx \leq b^Ty$
- Proof: Since $x \ge 0$ and $y \ge 0$, $c^T x \le y^T A x \le y^T b = b^T y$

Strong Duality

$\begin{array}{ll} & & & & & \\ \text{Primal} & & & & \\ \text{Max } c^Tx & & & \text{Min } b^Ty \\ \text{subject to } Ax \leq b & & \text{subject to } A^Ty \geq c \\ & & & & & \\ x \geq 0 & & & & \\ \end{array}$

• (Strong Duality) If primal is feasible and bounded (i.e., optimal value is not ∞), then dual is feasible and bounded. If x^* is optimal solution to the primal, and y^* is optimal solution to dual, then

$$c^{T}x^{*} = b^{T}y^{*}$$

• To prove x^* is optimal, I can give you y^* and you can check if x^* is feasible for the primal, y^* is feasible for the dual, and $c^Tx^*=b^Ty^*$

Consequences of Duality

$P \backslash D$	I	O	$oxed{U}$
I	?	?	?
O	?	?	?
U	?	?	?

I means infeasible
O means feasible and bounded
U means unbounded

Which combinations are possible?

Consequences of Duality

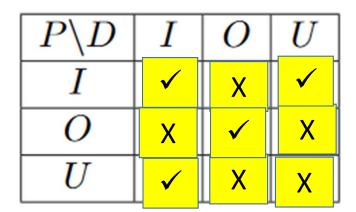

$P \backslash D$	I	O	$\mid U \mid$
I	✓	X	√
0	X	√	X
U	✓	X	X

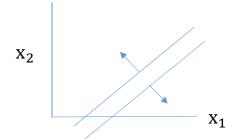

I means infeasible
O means feasible and bounded
U means unbounded

Check means possible X means impossible

Possible Scenarios

- Suppose primal is feasible and bounded
- By strong duality, dual is feasible and bounded
- If primal (maximization) is unbounded, by weak duality, $c^Tx \le b^Ty$, so no feasible dual solution e.g., $\max x_1$ subject to $x_1 \ge 1$ and $x_1 \ge 0$

- Can primal and dual both be infeasible?
- Primal: max $2x_1 x_2$ subject to $x_1 x_2 \le 1$ and $-x_1 + x_2 \le -2$ and $x_1 \ge 0$, $x_2 \ge 0$
- Dual: $y_1 \ge 0$, $y_2 \ge 0$, and $y_1 y_2 \ge 2$ and $-y_1 + y_2 \ge -1$, and min $y_1 2y_2$
- Constraints are same for primal and dual, and both infeasible

Strong Duality Intuition

maximize x_2

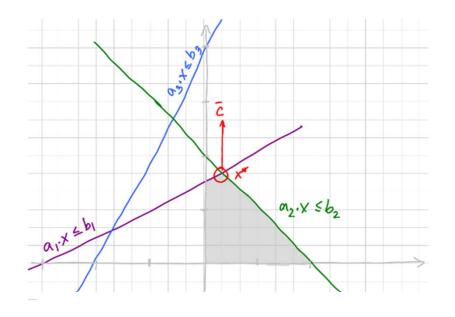

subject to
$$-x_1 + 2x_2 \le 3$$

 $x_1 + x_2 \le 2$
 $-2x_1 + x_2 \le 4$
 $x_1, x_2 \ge 0$

$$a_1 = (-1,2), b_1 = 3$$

 $a_2 = (1,1), b_2 = 2$
 $a_3 = (-2,1), b_3 = 4$

 x^* satisfies $a_1x = b_1$ and $a_2x = b_2$

Strong Duality Intuition

For non-negative y₁ and y₂

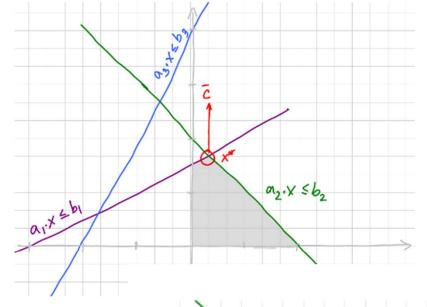

$$\mathbf{c} = y_1 \mathbf{a}_1 + y_2 \mathbf{a}_2.$$

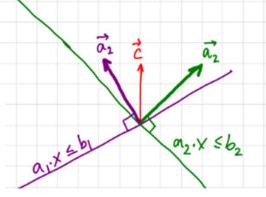

$$\mathbf{c}^{\mathsf{T}} \cdot \mathbf{x}^* = (y_1 \, \mathbf{a}_1 + y_2 \, \mathbf{a}_2) \cdot \mathbf{x}^*$$

= $y_1(\mathbf{a}_1 \cdot \mathbf{x}^*) + y_2(\mathbf{a}_2 \cdot \mathbf{x}^*)$
= $y_1b_1 + y_2b_2$

optimal value of primal = $\mathbf{c}^{\mathsf{T}}\mathbf{x}^* = \mathbf{b}^{\mathsf{T}}\mathbf{y} = \text{value of dual solution } \mathbf{y}$.

the y we found satisfies $\mathbf{c} = y_1 \mathbf{a}_1 + y_2 \mathbf{a}_2 = \sum_i y_i \mathbf{a}_i = A^T \mathbf{y}$, and hence y satisfies the dual constraints $\mathbf{y}^T A \ge \mathbf{c}^T$ by construction. But $\mathbf{b}^T \mathbf{y} \ge \mathbf{c}^T \mathbf{x}^*$ by weak duality, so y is optimal!

Duality in Zero-Sum Games

- R is an n x m row payoff matrix
- W.I.o.g. R has all non-negative entries
- Variables: $v, p_1, ..., p_n$
- Max v $\text{subject to } p_i \geq 0 \text{ for all rows i, } \sum_i p_i = 1 \text{ , } \sum_i p_i R_{i,j} \geq v \text{ for all columns j}$
- Replace $\sum_i p_i = 1$ with $\sum_i p_i \leq 1$.
- Include $v \ge 0$
- Write $\sum_i p_i R_{i,j} \ge v$ as $v \sum_i p_i R_{i,j} \le 0$

Duality in Zero-Sum Games

 $\max c^T x$ subject to $Ax \le b$ and $x \ge 0$

$$\mathbf{x} = \begin{bmatrix} v \\ p_1 \\ p_2 \\ \dots \\ p_n \end{bmatrix}, \mathbf{c} = \begin{bmatrix} 1 \\ 0 \\ 0 \\ \dots \\ 0 \end{bmatrix}, \mathbf{b} = \begin{bmatrix} 0 \\ 0 \\ \dots \\ 0 \\ 1 \end{bmatrix}, \text{ and } A = \begin{bmatrix} 1 \\ 1 \\ \dots \\ 1 \end{bmatrix} -R^T$$

- Dual: min y^Tb subject to $y^TA \ge c^T$ and $y \ge 0$ for $y = (y_1, ..., y_{m+1})$
- Dual constraints say $y_1+\cdots+y_m\geq 1$ and $\sum_j y_j R_{ij}\leq y_{m+1}$ for all rows i
 - Since we're minimizing y_{m+1} and $R_{i,j}$ all non-negative, $y_1 + ... + y_m = 1$
- y_{m+1} is value to the row player and y_1, \ldots, y_m is column player's strategy
- Strong duality: $\max_{p} \min_{j} \sum_{i} p_{i} R_{ij} = \min_{y_{1},..,y_{m}} \max_{i} \sum_{j} y_{j} R_{ij}$
